Chapter 2: Variables and Data Types

A variable is a name that refers to a value. You create one with the equals sign, and Python works out the type by itself. The basic data types are int for whole numbers, float for decimals, str for text and bool for True or False. The type function tells you the type of a value.

```
age = 21
name = 'Ayat'
print(type(age))
```

Chapter 2: Variables and Data Types

A list is an ordered, mutable collection written with square brackets, so you can add or change items. A tuple is ordered but immutable, written with round brackets, so it cannot change after creation. A dictionary stores key value pairs and a set stores unique items.

```
nums = [1, 2]; nums.append(3)
point = (3, 4)
d = {'a': 1}
```
