Chapter 5: Functions

A function is a reusable block of code defined with the def keyword. It can take parameters as inputs and it hands a result back with the return statement. Calling the function runs its code with the values you pass in.

```
def add(a, b):
    return a + b
print(add(2, 3))
```

Chapter 5: Functions

Parameters can have default values, and variables created inside a function are local, meaning they exist only while the function runs. A function without a return statement gives back None.

```
def greet(name='friend'):
    return 'Hi ' + name
```
